Problem 2

- * spherical asteroid
- * Ceres size $R_a = 1000$ km
- * transiting a Sun

Q1) what fraction of light is removed by the asteroid transit?

before transit $F_{\text{before}} = B_s \pi R_s^2$ surface emitting

in transit $F_{\text{transit}} = B_s \pi R_s^2 - B_s \pi R_a^2$ star blackbody emission or flux density

Normalized $\Delta = \frac{F_{\text{before}} - F_{\text{transit}}}{F_{\text{before}}} = \frac{R_a^2}{R_s^2} \propto 10^{-6}$

Q2) Assume JUST has a 30 ppm uncertainty on this signal, (what is the ~~SNR~~ signal to noise of this observation) can we detect this asteroid?

$$\text{SNR} = \frac{10^{-6}}{30 \cdot 10^{-6}} \propto 0.03!$$

an SNR about 5 is required
